Recurrent Kernel Networks

Dexiong Chen [†] Laurent Jacob [‡] Julien Mairal [†]

[†]Inria - firstname.lastname@inria.fr [‡]CNRS - firstname.lastname@univ-lyon1.fr

Overview

Kernel **supervised learning** for sequence objects

$$\min_{f\in\mathcal{H}} \frac{1}{n}\sum_{i=1}^{n} L(y_i, f(\mathbf{x}_i)) + \frac{\mu}{2}\|f\|_{\mathcal{H}}^2$$

- $\mathbf{x}_1, \dots \mathbf{x}_n \in \mathcal{X}$ are sequences (biological sequences or texts).

Goal: learning a predictive and interpretable function f.

From k-mers to gap-allowed k-mers modeling

Convolutional kernel networks [1] that model k-mers:

$$K_{\text{CKN}}(\mathbf{x}, \mathbf{x}') = \sum_{i=1}^{|\mathbf{x}|}\sum_{j=1}^{|\mathbf{x}'|} K_0\left(\mathbf{x}[i:i+k], \mathbf{x}'[j:j+k]\right)$$

- K_0 is a Gaussian kernel over one-hot representations of k-mers.
- A natural feature map of $\mathbf{x}$ is $\sum_{j=1}^{|\mathbf{x}|}\varphi_0(\mathbf{x}[j:j+k])$ with φ_0 the kernel mapping associated to K_0.
- Scalable and data or task-adaptive with Nyström approximation. Interpretable using end-to-end training with few filters.
- Unable to capture gappy motifs.

Recurrent kernel networks that generalize k-mers with gaps:

$$K_{\text{RKN}}(\mathbf{x}, \mathbf{x}') = \sum_{\mathbf{i}\in\mathcal{I}(k,|\mathbf{x}|)}\sum_{\mathbf{j}\in\mathcal{I}(k,|\mathbf{x}'|)} \lambda_{\mathbf{i},|\mathbf{x}|}\lambda_{\mathbf{j},|\mathbf{x}'|} K_0(\mathbf{x}[\mathbf{i}], \mathbf{x}'[\mathbf{j}])$$

- Take gapped k-mers into account. $\lambda_{\mathbf{j},|\mathbf{x}'|}$ penalizes the gaps, *e.g.* $\lambda_{\mathbf{j},|\mathbf{x}'|} = \lambda^{\text{gaps}(\mathbf{i})}$.
- A nature feature map is $\sum_{\mathbf{i}\in\mathcal{I}(k,|\mathbf{x}|)}\lambda_{\mathbf{i},|\mathbf{x}|}\varphi_0(\mathbf{x}[\mathbf{i}])$.
- Computationally fast using dynamic programming.
- The gate components in RNNs play the same role as gap penalization in substring kernels.

Definition of gap-allowed k-mers

- For $1 \le k \le n \in \mathbb{N}$, we denote by $\mathcal{I}(k,n)$ the set of sequences of indices with k elements $\mathbf{i} = (i_1, \dots, i_k)$, with $1 \le i_1 < \cdots < i_k \le n$.
- For a sequence $\mathbf{x} = x_1 \dots x_n \in \mathcal{X}$ of length n, for a sequence of indices $\mathbf{i} \in \mathcal{I}(k,n)$, we define a k-substring as:

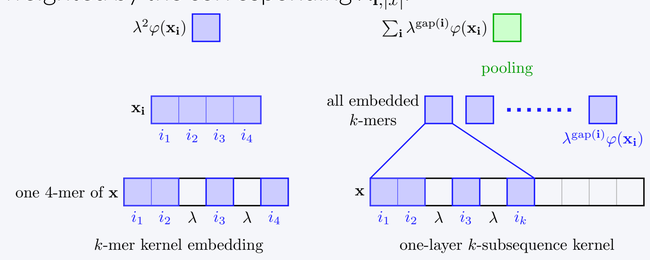
$$\mathbf{x}[\mathbf{i}] = x_{i_1}x_{i_2}\dots x_{i_k}.$$

- The length of the gaps in the substring is

$$\text{gaps}(\mathbf{i}) = i_k - i_1 - k + 1.$$

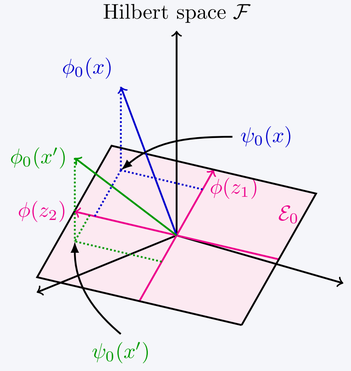
A feature map of RKN

- A feature vector of RKN for x is a mixture of Gaussians centered at $x[\mathbf{i}]$, weighted by the corresponding $\lambda_{\mathbf{i},|x|}$.



Nyström approximation and RNNs

Nyström approximation:



$\mathcal{E}_0 = \text{span}(\varphi_0(z_1), \dots, \varphi_0(z_q))$
$\psi_0(x) := K_{ZZ}^{-\frac{1}{2}}K_Z(x)$
where $[K_{ZZ}]_{ij} = K_0(z_i, z_j)$
and $[K_Z(x)]_i = K_0(z_i, x)$.

Given a set of anchor points $Z = (z_1, \dots, z_q)$ with $z_i \in \mathbb{R}^{k\times d}$, we project $\varphi_0(x)$ orthogonally onto $\mathcal{E}_0$ such that $K_0(x,x') \approx \langle\psi_0(x), \psi_0(x')\rangle$. Then we obtain an approximate feature map for K_{RKN}

$$\psi_k(\mathbf{x}) = \sum_{\mathbf{i}\in\mathcal{I}(k,|\mathbf{x}|)} \lambda_{\mathbf{i},|\mathbf{x}|}\psi_0(\mathbf{x}[\mathbf{i}]) = K_{ZZ}^{-\frac{1}{2}}\sum_{\mathbf{i}\in\mathcal{I}(k,|\mathbf{x}|)} \lambda_{\mathbf{i},|x|}K_Z(\mathbf{x}[\mathbf{i}]). \quad (1)$$

Fast computation with dynamic programming:
For any $j \in \{1, \dots, k\}$ and $t \in \{1, \dots, |\mathbf{x}|\}$,

$$\psi_j(\mathbf{x}_{1:t}) = K_{Z_jZ_j}^{-\frac{1}{2}}\begin{cases}\mathbf{c}_j[t] & \text{if } \lambda_{\mathbf{i},|\mathbf{x}|} = \lambda^{|\mathbf{x}|-i_1-j+1},\\ \mathbf{h}_j[t] & \text{if } \lambda_{\mathbf{i},|\mathbf{x}|} = \lambda^{\text{gaps}(\mathbf{i})},\end{cases}$$

where $\mathbf{c}_j[t]$ and $\mathbf{h}_j[t]$ in $\mathbb{R}^q$ obeying the recursion

$$\begin{aligned}
&\mathbf{c}_j[1] = \mathbf{h}_j[1] = 0 && 1 \le j \le k,\\
&\mathbf{c}_0[t] = 1 && 1 \le t \le |\mathbf{x}| - 1,\\
&\mathbf{c}_j[t] = \lambda\mathbf{c}_j[t-1] + \mathbf{c}_{j-1}[t-1] \odot \kappa(Z_j\mathbf{x}_t) && 1 \le j \le k,\\
&\mathbf{h}_j[t] = \mathbf{h}_j[t-1] + \mathbf{c}_{j-1}[t-1] \odot \kappa(Z_j\mathbf{x}_t) && 1 \le j \le k,
\end{aligned} \quad (2)$$

where κ is a non-linear function $\kappa(x) = e^{\alpha(x-1)}$ and Z_j is a matrix in $\mathbb{R}^{qd}$ whose i-th row is the j-th row of z_i.

Learning strategies

The supervised learning problem becomes

$$\min_{\mathbf{w}\in\mathbb{R}^q} \frac{1}{n}\sum_{i=1}^{n} L\left(\langle\psi_k(\mathbf{x}^i), \mathbf{w}\rangle, y^i\right) + \frac{\mu}{2}\|\mathbf{w}\|^2, \quad (3)$$

where ψ_k depends on Z. The model can be trained in 2 ways:

- **Unsupervised:** learning Z with K-means using (subsampled) k-mers (eventually with gaps). Then train a linear classifier.
- **Supervised:** jointly learning Z and $\mathbf{w}$ with SGD.

Max pooling in RKHS and extensions

- The sum can be replaced by a max, the corresponding recursive equations can be obtained by replacing all the sum with max.
- **Generalized max pooling** (GMP): build a representation φ_{gmp} such that $\langle\varphi_{\text{gmp}}, \varphi_i\rangle_{\mathcal{H}} = 1$ for a set of features $(\varphi_1, \dots, \varphi_N)$ in $\mathcal{H}^N$.
- Multilayer extension and link with string kernels can be found in [1].

Experiments

Protein fold recognition on SCOP 1.67
